

CDS 101/110a: Lecture 7-1 Loop Analysis of Feedback Systems

Douglas G. MacMartin

Goals:

- Compute closed loop stability from open loop properties:
 - Nyquist stability criterion for stability of feedback systems
- Define gain and phase margin and determine it from Nyquist and Bode plots

Reading:

- Åström and Murray, *Feedback Systems*, Ch 9.1-9.4
- *Advanced*: Lewis, Chapter 7

11/12/2012

Review From Last Week

$$u = A \sin(\omega t) \rightarrow \begin{cases} \dot{x} = Ax + Bu \\ y = Cx + Du \\ x(0) = 0 \end{cases} \rightarrow y_{ss} = A \cdot |G(i\omega)| \times \sin(\omega t + \arg G(i\omega))$$

$$G(s) = C(sI - A)^{-1}B + D$$

$$G_{y_2 u_1} = G_{y_2 u_2} G_{y_1 u_1} = \frac{n_1 n_2}{d_1 d_2}$$

Closed Loop Stability

Q: how do open loop dynamics affect the closed loop stability?

- Given open loop transfer function $C(s)P(s)$ determine when system is stable

Brute force answer: compute poles of closed loop transfer function

$$H_{yr} = \frac{PC}{1 + PC} = \frac{n_p n_c}{d_p d_c + n_p n_c}$$

- Poles of H_{yr} = zeros of $1 + PC$
- Easy to compute, but not so good for design

Alternative: look for conditions on PC that lead to instability

- Example: if $PC(s) = -1$ for some $s = i\omega$, then system is *not* asymptotically stable
- Condition on PC is much nicer because we can *design* $PC(s)$ by choice of $C(s)$
- However, checking $PC(s) = -1$ is not enough; need more sophisticated check

3

Game Plan: Frequency Domain Design

- Goal: figure out how to *design* $C(s)$ so that (i) closed-loop system is stable and (ii) we get good performance

$$H_{yr} = \frac{PC}{1 + PC}$$

- Poles of H_{yr} = zeros of $1 + PC$
- Would also like to “shape” H_{yr} to specify performance at different frequencies

- Low frequency range:

$$PC \gg 1 \Rightarrow \frac{PC}{1 + PC} \simeq 1$$

(good tracking)

- Bandwidth: frequency at which closed loop response = $1/\sqrt{2}$ \Rightarrow open loop gain ≈ 1
- Idea: use $C(s)$ to *shape* PC (under certain constraints)
- Need tools to analyze stability and performance for closed loop given PC

6

Nyquist Criterion

- Nyquist "D" contour
- Take limit as $r \rightarrow 0, R \rightarrow \infty$
- Trace from $-\infty$ to $+\infty$ along imaginary axis

Determine stability from (open) loop transfer function, $L(s) = P(s)C(s)$.

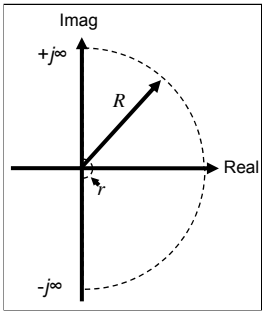

- Use "principle of the argument" from complex variable theory

Thm (Nyquist). Consider the Nyquist plot for loop transfer function $L(s)$. Let

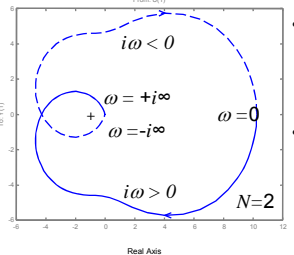

- P # RHP poles of $L(s)$
- N # clockwise encirclements of -1
- Z # RHP zeros of $1 + L(s)$

Then

$$Z = N + P$$

Nyquist Diagrams
From: U(1)

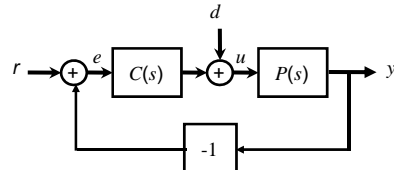

- Trace frequency response for $L(s)$ along the Nyquist "D" contour
- Count net # of clockwise encirclements of the -1 point

7

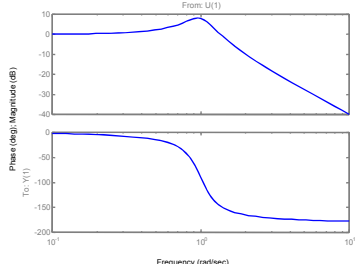

Simple Interpretation of Nyquist

- Basic idea: avoid positive feedback
 - If $L(s)$ has 180° phase (or greater) and gain greater than 1, then signals are amplified around loop
 - Use when phase is monotonic
 - General case requires Nyquist

Can generate Nyquist plot from Bode plot + reflection around real axis

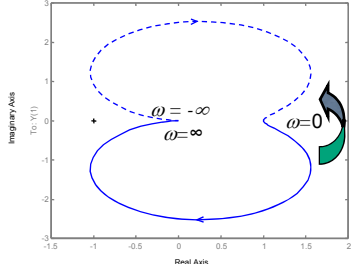

Bode Diagrams
From: U(1)

ambode(sys) [or bode(sys) in dB]

D. MacMartin, CDS 101/110a 2012
8

Example: Proportional + Integral* speed controller

Nyquist Diagrams

$$P(s) = \frac{1/m}{s + b/m} \times \frac{r}{s + a}$$

$$C(s) = K_p + \frac{K_i}{s + 0.01}$$

Remarks

- $N = 0, P = 0 \Rightarrow Z = 0$ (stable)
- Need to zoom in to make sure there are no net encirclements
- Note that we don't have to compute closed loop response

* slightly modified; more on the design of this compensator in next week's lecture

9

More complicated systems

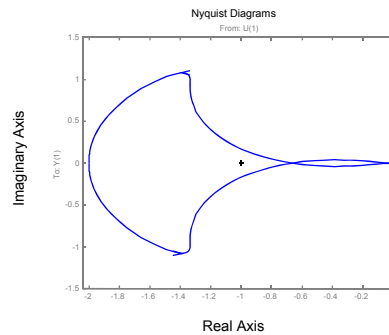

- What happens when open loop plant has RHP poles?
 - $1 + PC$ has singularities inside D contour \Rightarrow these must be taken into account

$$L(s) = \frac{s + 1}{s - 0.5} \times \frac{1}{s^2 + s + 1}$$

unstable pole

$$\frac{1}{1 + L} = \frac{s + 1}{(s + 0.35)(s + 0.07 + 1.2i)(s + 0.07 - 1.2i)} \checkmark$$

$$N = -1, P = 1 \Rightarrow Z = N + P = 0 \text{ (stable)}$$

D. MacMartin, CDS 101/110a 2012

10

Comments and cautions

- Why is the Nyquist plot *useful*?
 - Old answer: easy way to compute stability (before computers and MATLAB)
 - Real answer: gives *insight* into stability and robustness; very useful for reasoning about stability

- Nyquist plots for systems with poles on the $j\omega$ axis

- chose contour to avoid poles on axis
- need to carefully compute Nyquist plot at these points
- evaluate $H(\epsilon+0i)$ to determine direction

- Cautions with using MATLAB
 - MATLAB doesn't generate portion of plot for poles on imaginary axis
 - These must be drawn in by hand (make sure to get the orientation right!)

D. MacMartin, CDS 101/110a 2012

11

Robust stability: gain and phase margins

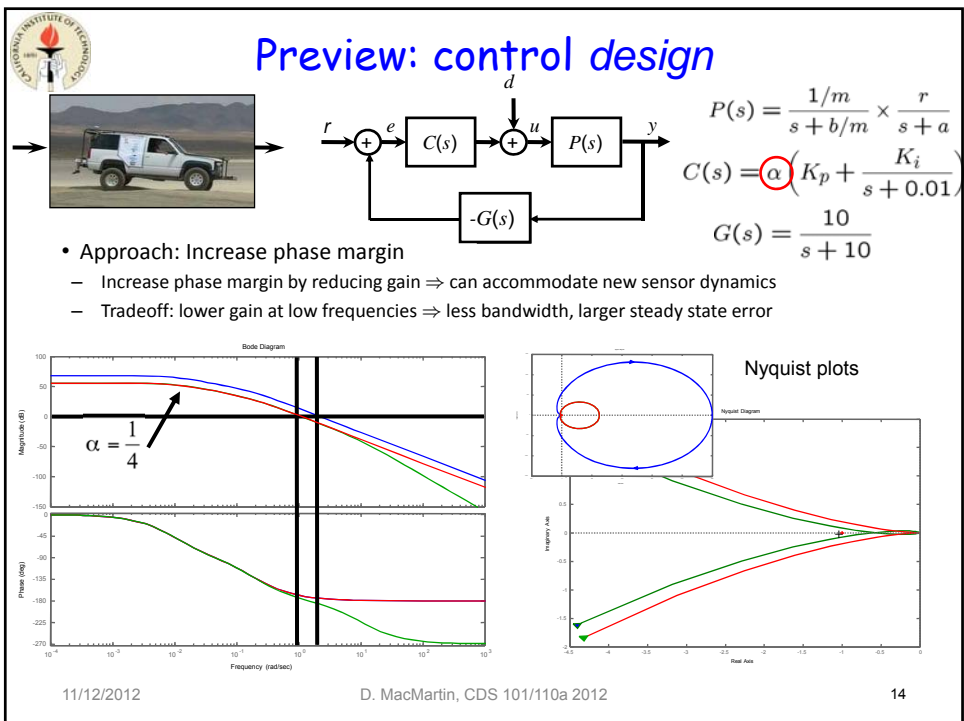

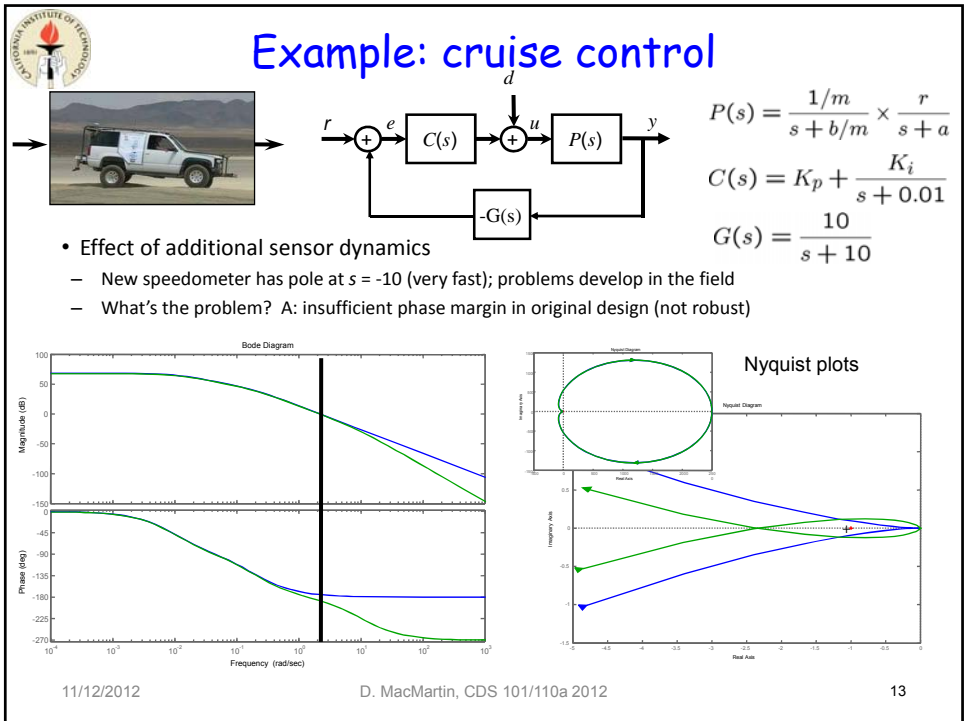

- Nyquist criterion tells us if closed loop is stable, but not *how* stable
- Gain margin
 - How much we can modify the *loop gain* and still have the system be stable
 - Determined by the location where the loop transfer function crosses 180° phase
- Phase margin
 - How much we can add “phase delay” and still have the system be stable
 - Determined by the phase at which the loop transfer function has unity gain
- Bode plot interpretation
 - Look for gain = 1, 180° phase crossings
 - MATLAB: margin(sys)

11/12/2012

D. MacMartin, CDS 101/110a 2012

12

Summary: Loop Analysis of Feedback Systems

- Nyquist criteria for loop stability
- Gain, phase margin for robustness

Thm (Nyquist).
 P # RHP poles of $L(s)$
 N # CW encirclements
 Z # RHP zeros of $1+L$
 $Z = N + P$

Announcements

- Midterm averages:
 - CDS 110a: 43/50
 - CDS 101: 29/35
- Homework #6 available on the web tonight

Computing your course grade so far:

$$\text{Grade} = \frac{5/9}{4} \times \sum_{i=1}^4 \left(\frac{\text{HW}_i}{\text{max}_i} \right) + (4/9) \times \frac{\text{MT}}{\text{max}_{\text{mt}}}$$
