R. M. Murray | **Problem Set #8** | Issued: 28 Nov 2012
Fall 2012 | | Due: 7 Dec 2012

Note: In the upper left hand corner of the *second* page of your homework set, please put the number of hours that you spent on this homework set (including reading).

1. Consider the problem of stabilizing the orientation of a flying insect, modeled as a rigid body with moment of inertia $J = 0.41$ and damping constant $D = 1$.[1] We assume there is a small delay $\tau = 0.01$ seconds given by the neural circuitry that implements the control system. The resulting transfer function for the system is taken to be

$$P(s) = \frac{1}{Js^2 + Ds} e^{-\tau s}.$$

   (a) Suppose that we can measure the orientation of the insect relative to its environment and we wish to design a control law that that gives zero steady state error, less than 10% tracking error from 0 to 0.5 Hz and has a phase margin of at least 60°. Convert these specifications to appropriate bounds on the loop transfer function and sketch the resulting constraints on a Bode plot.

   (b) Using a lead compensator, design a controller that meets the specifications in part (a). Provide whatever plots are required to verify that the specification is met. You may use a Padé approximation for the time delay, but make sure that it is a good approximation over a frequency range that includes your gain crossover frequency.

   (c) Plot or sketch the Nyquist plot corresponding to your controller and the process. You can again use a Padé approximation for the time delay.

   (d) Extra credit: genetically modify a fly to implement your controller, using the fly visual system as your input.

Problem Set #8

R. M. Murray
Fall 2012

Issued: 28 Nov 2012
Due: 7 Dec 2012

Note: In the upper left hand corner of the *second* page of your homework set, please put the number of hours that you spent on this homework set (including reading).

1. Consider a control system with process and controller dynamics given by

$$P(s) = \frac{1}{s(s+c)} \qquad C(s) = k.$$

where $k > 0$.

(a) Show that the closed loop response of the system can be written as

$$G(s) = \frac{\omega_0^2}{s^2 + 2\zeta\omega_0 s + \omega_0^2}$$

and give formulas for ζ and ω_0 in terms of c and k.

(b) Show that the phase margin for the system is given by

$$\varphi_m = \tan^{-1}\Big(\frac{2\zeta}{\sqrt{\sqrt{1+4\zeta^4} - 2\zeta^2}}\Big)$$

(Hint: compute the frequency at which $|L(i\omega)| = 1$ and then find the phase at that frequency.)

(c) Show that the overshoot for the closed loop step response is given by

$$M_p = \begin{cases} e^{-\pi\zeta/\sqrt{1-\zeta^2}} & \text{for } |\zeta| < 1 \\ 0 & \text{for } \zeta \geq 1. \end{cases}$$

(Hint: use the form of the solution from equation (6.24) and search for the shortest time when $\dot{y}(t) = 0$.)

(d) Use the formulas from parts 1b and 1c to plot M_p as a function of φ_m for ζ in the range $0 < \zeta \leq 1$.

2. Consider the problem of stabilizing the orientation of a flying insect, modeled as a rigid body with moment of inertia $J = 0.41$ and damping constant $D = 1$.[2] We assume there is a small delay $\tau = 0.01$ sgiven by the neural circuitry that implements the control system. The resulting transfer function for the system is taken to be

$$P(s) = \frac{1}{Js^2 + Ds} e^{-\tau s}.$$

[2] Based loosely on "Biologically Inspired Feedback Design for Drosophila Flight", M. Epstein, S. Waydo, S. B. Fuller, W. Dickson, A. Straw, M. H. Dickinson and R. M. Murray, 2007 American Control Conference.

(a) Suppose that we can measure the orientation of the insect relative to its environment and we wish to design a control law that gives zero steady state error, less than 10% tracking error from 0 to 0.5 Hz and has an overshoot of no more than 10%. Convert these specifications to appropriate bounds on the loop transfer function and sketch the resulting constraints on a Bode plot. (Hint: Try using problem 1 to convert the overshoot requirement to a phase margin requirement.)

(b) Using a lead compensator, design a controller that meets the specifications in part (a). Provide whatever plots are required to verify that the specification is met. You may use a Padé approximation for the time delay, but make sure that it is a good approximation over a frequency range that includes your gain crossover frequency.

(c) Plot or sketch the Nyquist plot corresponding to your controller and the process. You can again use a Padé approximation for the time delay. Show the gain and phase margin on your plot.

(d) Plot the "gang of 4" for the system. If any of the magnitudes of the closed loop transfer functions are substantially greater than one in some frequency range, explain the consequences of this in terms of one of the input/output responses of your system. (You are not required to fix these problems.)

(e) Extra credit: genetically modify a fly to implement your controller, using the fly visual system as your input.

3. Consider the dynamics of the magnetic levitation system from lecture. The transfer function from the electromagnet input voltage to the IR sensor output voltage is given by

$$P(s) = \frac{k}{s^2 - r^2}$$

with $k = 4000$ and $r = 25$ (these parameters are slightly different than those used in the MATLAB files distributed with the lecture).

(a) Design a stabilizing compensator for the process, assuming unity feedback. Compute the poles and zeros for the loop transfer function and for the closed loop transfer function between the reference input and measured output.

(b) Plot the Nyquist plot corresponding to your compensator and the process dynamics, and verify that the Nyquist criterion is satisfied.

(c) Plot the log of the magnitude of the sensitivity function, $\log |S(j\omega)|$, versus ω on a *linear* scale and numerically verify that the Bode integral formula is (approximately) satisfied. (Hint: you can do the integration numerically in MATLAB, using the `trapz` function. Make sure to choose your frequency range sufficiently large.)
