Nonlinearity **10** 223-242

Abstract

We use so-called energy dependent Schrödinger operators to establish a link between special classes of solutions of N -component systems of evolution equations and finite dimensional Hamiltonian systems on the moduli spaces of Riemann surfaces. We also investigate the phase space geometry of these Hamiltonian systems and introduce deformations of the level sets associated to conserved quantities, which results in a new class of solutions with monodromy for N -component systems of pde's.

After constructing a variety of mechanical systems related to the spatial flows of nonlinear evolution equations, we investigate their semiclassical limits. In particular, we obtain semiclassical asymptotics for the Bloch eigenfunctions of the energy dependent Schrödinger operators, which is of importance in investigating zero-dispersion limits of N -component systems of pde's.

Contents

1 Introduction

There are several circumstances in which semiclassical solutions and techniques are used for nonlinear evolution equations. Of particular interest is the zero-dispersion limit. Direct asymptotic expansions of the evolution equations typically yield equations of hydrodynamic type. More sophisticated techniques for integrable systems employ limiting techniques and WKB analysis in the context of the inverse scattering theory (see Lax and Levermore I, II, III [1983], Venakidis [1987] and for a survey see Lax, Levermore and Venakidis [1993]). The structure of integrable equations can also be exploited using complex geometric asymptotics in this limit (see Alber [1989, 1991] and Alber and Marsden [1992]).

Jin, Levermore and McLaughlin [1994] use a WKB-type expansion for the associated scattering equations of the (d)NLS (defocusing nonlinear Schrödinger) equation and obtain equations for the conserved quantities in Riemann invariant form for the semiclassical limit ($\hbar \rightarrow 0$). This work was extended in Bronski and McLaughlin [1994] who described the formation of caustics in a numerical context and showed that an extension of hydrodynamic type equations must be used to adequately account for the modulational instability of the (f)NLS (focusing nonlinear Schrödinger) equation.

There have been many important developments in which the methods of complex and algebraic geometry have been used to investigate the eigenfunctions of Hill's operator in the context of integrable equations. For example, Bloch eigenfunctions of Hill's operators, which are meromorphic on the associated spectral curves play an important role in the inverse scattering transform method for nonlinear soliton equations. For details see Ablowitz and Segur [1981], Newell [1985] and Ablowitz and Clarkson [1991].

Connections have also been established between special classes of solutions of many nonlinear equations and finite dimensional mechanical systems. Moser [1980,1981] and Knörrer [1982] used one-dimensional Schrödinger equations with finite gap potentials (having a finite number of bands of continuous spectrum) and reflectionless potentials (having a finite number of elements of discrete spectrum) to demonstrate a connection between the classical C. Neumann problem and quasi-periodic and soliton solutions of the KdV equation. They also established a connection between the C. Neumann problem and the Jacobi problem of geodesics on quadrics.

For the C. Neumann problem, the spectral parameter appears linearly in the potential of the corresponding Schrödinger equation: $V = u - \lambda$. In contrast, Antonowicz and Fordy [1987a,b, 1988, 1989] and Antonowicz, Fordy and Liu [1991] investigated potentials with poles in the spectral parameter for what they refer to as *energy dependent* Schrödinger operators connected to certain systems of evolution equations. Specifically, they obtained multi-Hamiltonian structures for N -component integrable systems of equations related to the following isospectral eigenvalue problem:

$$L\psi = \left(\frac{\partial^2}{\partial x^2} + \frac{V}{K} \right) \psi = 0, \quad (1)$$

$$K = \sum_{j=0}^M k_j \lambda^j; \quad V = \sum_{j=0}^N v_j(x, t) \lambda^j, \quad (2)$$

where the k_j are constants and the $v_j(x, t)$ are functions of the variable x , the parameter t and the spectral parameter λ is complex. This includes the coupled KdV and Dym systems. The presence of a pole in the potential was shown in Alber, Camassa, Holm and Marsden [1994b, 1995] to be essential for the existence of weak billiard solutions of the nonlinear equations including the Dym equation and equations in its hierarchy. The weak billiard solutions can be obtained for all N -component systems.

Well known techniques exist for establishing a link between mechanical systems and their quantum mechanical counterparts. One such technique uses the WKB method to analyze asymptotic limits and thereby establish the corresponding semiclassical solutions (modes). In this paper we use this technique to establish certain semiclassical limits of the

spatial flows related to integrable nonlinear evolution equations. In this way we establish a connection between special classes of solutions of nonlinear equations and mechanical systems to form a semiclassical theory for these nonlinear equations.

In what follows we make several points. We use energy dependent Schrödinger operators of the type (??) and their associated spectral curves to establish a link between special classes of solutions of N -component systems of evolution equations and finite-dimensional Hamiltonian systems on Riemann surfaces. We apply special limiting procedures (involving the coalescence of roots of the basic polynomial of the spectral curve) to quasi-periodic solutions to obtain a system with monodromy. This provides an example of a system of pde's with monodromy. Prior to this, such effects were related to mechanical systems and their quantum counterparts such as the classical and quantum spherical pendulum (see Cushman and Duistermaat [1988], Duistermaat [1988], and Alber and Marsden [1996]).

We also describe several mechanical systems that are associated with different classes of solutions of N -component systems. All of these systems admit a geometric interpretation in the form of geodesic flows on n -dimensional pseudo-spheres in the fields of different potentials. Therefore they can be linked to the Laplace Beltrami operators in a way similar to the method of geometric optics. These systems are solved using algebraic geometric methods, and semiclassical approximations for eigenfunctions of Laplace Beltrami operators having the form of complex WKB modes are studied. Using these elements we proceed to investigate the monodromy of the semiclassical approximation to the spectrum.

To investigate the zero-dispersion limit of N -component systems one considers the class of generalized Schrödinger equations

$$L\psi = \left(K \frac{\partial^2}{\partial x^2} + V \right) \psi = 0 , \quad (3)$$

where

$$K = \sum_{j=0}^M k_j \epsilon^j , \quad V = \sum_{j=0}^N v_j(x, t) \lambda^j . \quad (4)$$

These are similar to (??) and (??) except that the spectral parameters in the expansions of K and V now have a different form. The parameter ϵ will be our small parameter in this study. In this paper we investigate the asymptotic limit $\epsilon \rightarrow 0$ of the associated Bloch eigenfunctions. Using this idea, we link Jacobi geodesic flows on quadrics and the WKB approximation of the eigenfunctions of the stationary one-dimensional Schrödinger equation.

Finally, we introduce time t into the system as a parameter and describe the dependence of the WKB modes on this parameter.

2 Hamiltonian Systems on Riemann Surfaces and Solutions of Nonlinear Equations

First we recall a link between quasi-periodic and soliton solutions of integrable nonlinear equations and Hamiltonian systems on Riemann surfaces (see, for example, Alber, Camassa, Holm and Marsden [1994, 1995]) established using algebraic geometric methods

(see, amongst others, Ercolani and McKean [1990]). Both the inverse scattering transform method for integrable systems (see Ablowitz and Segur [1981]) and method of generating equations use a link between ends of the gaps of the continuous spectrum and elements of the discrete spectrum of the Schrödinger operators and first integrals for integrable systems. Potentials in the Schrödinger operator which yield finite gap structure of the spectrum and discrete spectrum are called finite gap potentials and reflectionless potentials respectively.

The quasi-periodic solutions of many integrable nonlinear equations can be described in terms of finite dimensional Hamiltonian systems on \mathbb{C}^{2n} . A complete set of first integrals for such equations can be obtained, for example, by the method of generating equations, as is summarized in Alber, Camassa, Holm and Marsden [1994, 1995]. The method of generating equations introduces a finite dimensional complex phase space \mathbb{C}^{2n} and two commuting Hamiltonian flows. The first Hamiltonian flow gives the spatial evolution, and the other gives the temporal evolution of special classes of solutions of the original partial differential equation. The level sets of the first integrals are Riemann surfaces having branch points parameterized by the choice of values of the first integrals.

Consider the finite gap spectrum of the operator (??). (For details about the time evolution of the eigenfunctions of generalized Schrödinger equations of this type and multi-Hamiltonian structures associated with them, see Antonowicz and Fordy [1988, 1989].) In some cases, such as the KdV equation, λ appears as an eigenvalue and one ultimately equates the potential with a quasi-periodic solution of the nonlinear equation itself. In other cases such as the NLS equation, a connection between the potential and solutions of the equations is more complicated but can be established using the method of generating equations.

To carry out the procedure, one begins by looking for a solution A of the Lax system

$$\left. \begin{array}{l} L\psi = 0 \\ \left(\frac{\partial L}{\partial t} + [L, A] \right) \psi = 0 \end{array} \right\} \quad (1)$$

of the form

$$A = B \frac{\partial}{\partial x} - \frac{1}{2} \frac{\partial B}{\partial x}, \quad (2)$$

where L is defined in (??). Substituting the given form of A into the Lax system, one obtains

$$\frac{\partial V}{\partial t} = -\frac{B'''}{2} + 2B' \frac{V}{K} + B \frac{V'}{K}, \quad (3)$$

where the prime denotes $\partial/\partial x$. In what follows we will also sometime use a dot to denote $\partial/\partial t$, so $\dot{V} = \partial V/\partial t$.

Equation (??) is called the *generating equation*. Expanding B and V in the parameter λ and equating like powers produces different hierarchies of integrable systems. In many cases these expansions are polynomial in λ with coefficients depending on functions v_j and a finite number of their space derivatives as well as one time derivative. Note that a fixed potential V produces a recurrence relation for one hierarchy of evolution equations. For instance, if we take B to be polynomial of degree n , defining $B = B_n = \sum_{j=0}^n b_j \lambda^{n-j}$, we obtain the n th system of evolution equations with dependent variables v_j (see (??)).

Stationary solutions of any member of the hierarchy such that $\partial V/\partial t = 0$ depend on B and V , but the evolution variable, t , becomes a parameter. Setting $\partial V/\partial t = 0$ in (??), multiplying by BK and integrating once produces the *stationary generating equation*,

$$K \left(-B''B + \frac{B'^2}{2} \right) + 2B^2V = C(\lambda) , \quad (4)$$

where $C(\lambda)$ is a polynomial in λ of order $(2n + N)$. A similar equation was first obtained in connection with the KdV equation in Gelfand and Dikey [1975] by investigating asymptotics of resolvents of the Sturm-Liouville equations.

The evolution of B is obtained using a *dynamic generating equation*. At each instant, that is for each value of the parameter t , B is a solution of the the stationary generating equation (??). Differentiating (??) with respect to t and requiring consistency with (??) yields,

$$\dot{B}_n = B'_n B_l - B'_l B_n, \quad i.e., \quad \frac{\partial}{\partial t} \left(\frac{1}{B_n} \right) = \frac{\partial}{\partial x} \left(\frac{B_l}{B_n} \right), \quad (5)$$

where $B_l = \sum_{j=0}^l b_j \lambda^{n-j}$ is a solution of the dynamical generating equation (??). This determines the time evolution of the functions B . A proof is given, for example, in Alber and Alber [1987] and Alber *et al.* [1994]. Here the n corresponds to the number of roots of the spectral polynomial. These may be endpoints of gaps or isolated poles corresponding to solitons. Thus, n is the dimension of the solution space and l labels the equation in the hierarchy.

To show how the generating equations yield the quasi-periodic n -gap solutions of evolution equations, one introduces the roots, μ , of $B = B_n = \prod_{j=1}^n (\lambda - \mu_j(x, t))$. Substituting $\lambda = \mu_j, j = 1, \dots, n$ one by one into (??) one obtains a system of ordinary differential equations for the spatial flow of the μ -variables:

$$\mu'_j = \frac{1}{\prod_{r \neq j}^n (\mu_j - \mu_r)} \sqrt{\frac{C(\mu_j)}{K(\mu_j)}}, \quad j = 1, \dots, n . \quad (6)$$

The motion in t is produced by substituting $\lambda = \mu_j$ with B this time in (??) so that,

$$\dot{\mu}_j = \frac{B_l(\mu_j)}{\prod_{r \neq j}^n (\mu_j - \mu_r)} \sqrt{\frac{C(\mu_j)}{K(\mu_j)}}, \quad j = 1, \dots, n . \quad (7)$$

Solutions of this system of equations for $\mu_j(x, t)$ can be related to the $v_j(x, t)$ to obtain solutions of the original hierarchies of evolution equations generated by (??). Basic facts about these systems are therefore of great interest. The systems (??) and (??) have a Hamiltonian structure with

$$H = \sum_{j=1}^n \frac{D(\mu_j) \left(P_j^2 - \frac{C(\mu_j)}{K(\mu_j)} \right)}{\prod_{r \neq j}^n (\mu_j - \mu_r)}, \quad j = 1, \dots, n , \quad (8)$$

where $D(\mu_j) = 1$ and $D(\mu_j) = B_l(\mu_j)$ in the stationary and dynamical cases, respectively. The two Hamiltonian flows have the same set of first integrals, whose zero level sets are,

$$P_j^2 = \frac{C(\mu_j)}{K(\mu_j)}, \quad j = 1, \dots, n. \quad (9)$$

One can think of \mathbb{C}^{2n} as being the cotangent bundle of \mathbb{C}^n , with configuration variables μ_1, \dots, μ_n and with canonically conjugate momenta P_1, \dots, P_n . The two commuting Hamiltonians on \mathbb{C}^{2n} both have the form

$$H = \frac{1}{2} g^{jj} P_j^2 + V(\mu_1, \dots, \mu_n), \quad (10)$$

where g^{jj} is a Riemannian metric on \mathbb{C}^n . The two Hamiltonians are distinguished by different choices of the metric but they have the same set of first integrals (??). Thus, two commuting flows are obtained on the symmetric product of n copies of the Riemann surface

$$\mathcal{R} : P^2 = \frac{C(\mu)}{K(\mu)}$$

defined by the first integrals. *It is called the spectral curve associated with the completely integrable problem.* Branch points of the Riemann surface are given by the roots of $C(\lambda)$ and $K(\lambda)$. (For details about completely integrable systems on complex tori see Ercolani and McKean [1990]). These Riemann surfaces can be regarded as complex Lagrangian submanifolds. *This is called the μ -representation of the problem.* Sometimes the μ variables are also called Dirichlet eigenvalues or an auxiliary spectrum. The μ variables move along cycles on the corresponding Riemann surface in accordance with the equations (??) and (??), which define their motion over the basic cuts on the Riemann surface whose endpoints are the endpoints of the gaps in the spectrum of the associated operator (??).

In the case of quasi-periodic and soliton solutions, one obtains compact and noncompact Riemann surfaces (see for example Alber and Marsden [1992, 1994] and §3 and §4 of this paper). The μ -representation yields complex angle representations on Jacobi varieties in a way described in Alber *et. al.* [1994, 1995]. This yields, amongst other things, a representation of the μ -variables in terms of θ and τ -functions (see McKean [1979] and Mumford [1983]). In the last step, the solution of the initial nonlinear equation is expressed in terms of the μ -variables.

In the μ -representation the calculation of modulation equations is facilitated. Whitham equations can be obtained in terms of holomorphic and meromorphic differentials. They describe the slow modulation of branch points on the Riemann surfaces (see Flaschka, Forest and McLaughlin [1980]). Notice that the monodromy effect to be described in §4 is important in investigating Whitham equations of N -component systems.

In the most general case, the μ -representation describes a geodesic flow for the metric $ds^2 = \sum_{j=1}^n g_{jj} \mu_j^2$ on complex Riemannian manifolds. Classification of all such metrics which yield separation of variables in Hamilton-Jacobi equations and integrability of the geodesic flows has been investigated recently in Benenti *et al.* [1995]. In the context of their paper μ -variables are viewed as generalized elliptic coordinates.

We will use this interpretation of the μ -variables in the next section to clarify a connection to mechanical systems. Namely, the procedure outlined in this section also produces many important classical as well as new integrable mechanical systems with Hamiltonians of the form (??) for particular choices of B and V . These expansions can also be used to obtain semiclassical solutions of the eigenvalue problem represented by L in (??) and yields asymptotics for the Bloch eigenfunctions. These finite dimensional representations also permit the analysis of a connection between caustic envelopes in the phase space of these mechanical systems and Maslov-Keller indices in the semiclassical approximation of the spectrum of the Laplace-Beltrami operators (see Alber [1989, 1991], Alber and Marsden [1992] and §6 and §7 of this paper).

3 The Family of Homoclinic Orbits Described as Hamiltonian Flows on a Riemann surface

Here we recall the μ representation for the quasi-periodic and homoclinic Hamiltonian flows of the classical C. Neumann problem of mechanics.

Devaney [1978] investigated homoclinic orbits of the C. Neumann problem. Moser [1981] studied equilibrium solutions possessing stable and unstable manifolds for this mechanical problem in connection with the spectral theory of finite gap and reflectionless potentials of Schrödinger operators and quasi-periodic and soliton solutions of the KdV equation. In particular, it was shown that equilibrium solutions are associated with the reflectionless potentials which correspond to a set of negative double points of the discrete spectrum.

Here we show that a special limiting process applied to the quasi-periodic μ representation leads to the introduction of a new set of first integrals and exponential Hamiltonians for homoclinic orbits. (See Alber and Marsden [1994] for details). This approach will be applied in the next section to the 2-component Dym system to describe special classes of solutions with monodromy.

The system of first integrals introduced by Devaney and Uhlenbeck (see Devaney [1978]) for the C. Neumann problem, namely

$$F_j(y, \dot{y}) : TS^n \rightarrow \mathbf{R} , \quad (1)$$

$$F_j(y, \dot{y}) = y_j^2 + \frac{1}{2} \sum_{k \neq j} \frac{(\dot{y}_j y_k - \dot{y}_k y_j)^2}{l_k^2 - l_j^2} , \quad j = 1, \dots, n \quad (2)$$

plays a central role in Devaney's [1978] description of transversal homoclinic orbits. Here

$$l_0 < l_1 < \dots < l_n \quad \text{and} \quad l_0 = 0 .$$

Namely, he proved that the first integrals are identically zero along the orbits; *i.e.*,

$$F_j(y, \dot{y}) = 0 , \quad j = 1, \dots, n . \quad (3)$$

We shall use this observation together with the μ representations for the quasi-periodic flows of the C. Neumann problem, *i.e.*, solutions of the system

$$\frac{\partial \mu_j}{\partial x} = 2 \frac{\sqrt{-\prod_{r=1}^n (\mu_j - m_r) \prod_{k=1}^{n+1} (\mu_j - a_k)}}{\prod_{i \neq j} (\mu_j - \mu_i)}, \quad j = 1, \dots, n. \quad (4)$$

In accordance with the general result described in §2, this system is defined on the the symmetric product

$$\Gamma : \quad (\mathfrak{R} \times \dots \times \mathfrak{R}) / \sigma_n \quad (5)$$

of n copies of the Riemannian surface

$$\mathfrak{R} : \quad P^2 = - \prod_{k=1}^{n+1} (\mu - a_k) \prod_{r=1}^n (\mu - m_r); \quad (6)$$

in fact, Γ is a Lagrangian submanifold of the phase space \mathbb{C}^{2n} . In this setting, the first integrals of the problem can be represented in the form

$$F_j = \frac{\prod_{r=1}^n (a_j - m_r)}{\prod_{k \neq j} (a_j - a_k)}. \quad (7)$$

Here,

$$a_j = -2l_j^2, \quad j = 0, \dots, n,$$

and the constants m_r and a_j are the endpoints of the gaps in the spectrum of the associated Schrödinger equation. Condition (??) and formula (??) yield the following choice of first integrals m_j :

$$m_j = a_j = b_j, \quad j = 1, \dots, n; \quad a_0 = 0, \quad (8)$$

which corresponds to a homoclinic orbit, meaning that all roots of the basic polynomial of the Riemannian surface (??) are double negative roots, except $a_0 = 0$.

The system (??) corresponding to the case of a singular spectrum (??) coincides with the system of equations describing profiles of the soliton solutions of the KdV equation; that is, with

$$\frac{\partial \mu_j}{\partial x} = 2 \frac{\sqrt{-\mu_j} \prod_{k=1}^n (\mu_j - b_k)}{\prod_{i \neq j} (\mu_j - \mu_i)}, \quad j = 1, \dots, n. \quad (9)$$

This system may be rewritten as

$$\frac{\partial \mu_j / \partial x}{(\mu_j - b_r)} = 2 \frac{\sqrt{-\mu_j} \prod_{k \neq r}^n (\mu_j - b_k)}{\prod_{i \neq j} (\mu_j - \mu_i)}, \quad j = 1, \dots, n; \quad r = 1, \dots, n. \quad (10)$$

Summing with respect to $j = 1, \dots, n$ for each r and integrating, one obtains the following angle variables

$$\theta_r = \sum_{j=1}^n \frac{1}{2} \int_{\mu_j^0}^{\mu_j} \frac{d\mu_j}{\sqrt{-\mu_j} (\mu_j - b_r)} = x + \theta_r^0, \quad r = 1, \dots, n. \quad (11)$$

The corresponding action function and action variables can be chosen as follows

$$S = \sum_{j=1}^n \frac{1}{2} \int_{\mu_j^0}^{\mu_j} \frac{\log(\mu_j - b_r) d\mu_j}{\sqrt{-\mu_j}}, \quad I_r = a_r, \quad r = 1, \dots, n. \quad (12)$$

This results in $\theta_r = -\partial S / \partial I_r$ and so leads to the following form of the first integrals:

$$P_j = \frac{\sum_{k=1}^n \log(\mu_j - b_k)}{2\sqrt{-\mu_j}}, \quad j = 1, \dots, n. \quad (13)$$

This gives a new Hamiltonian on \mathbb{C}^{2n} that is of exponential type for the system (??) describing the family of homoclinic orbits, namely

$$H = \frac{\sum_{j=1}^n (e^{2\sqrt{-\mu_j} P_j} - \bar{C}(\mu_j))}{\prod_{r \neq j} (\mu_j - \mu_r)}, \quad (14)$$

where $\bar{C}(\mu) = \prod_{k=1}^n (\mu - a_k)$. Note that the flow of (??) is defined on the noncompact level sets of (??) and it is linearized in terms of the angle variables (??).

The homoclinic angle representations (??) are defined on a noncompact Jacobi variety \mathcal{J} . The variety \mathcal{J} is defined by a generalized Abel Jacobi map (??), as in Ercolani [1989]. This map is associated with \mathfrak{R}^n , the symmetric product of n copies of the Riemann surface

$$\mathfrak{R}: \quad P = \frac{1}{2\sqrt{-\mu} \prod_{r=1}^n (\mu - b_r)}. \quad (15)$$

Let the double covering of \mathfrak{R}^n be denoted $\widetilde{\mathfrak{R}}^n$. This covering is defined by the following change of variables

$$\xi_j^2 = -\mu_j, \quad \beta_j^2 = -b_j, \quad j = 1, \dots, n. \quad (16)$$

The Hamiltonian (??) defines a dynamical system on \mathfrak{R}^n , which lifts to a dynamical system on $\widetilde{\mathfrak{R}}^n$. An analysis of the angle representation (??) shows that the system has a homoclinic point $b = (b_1, \dots, b_n)$ on \mathfrak{R}^n as $x \rightarrow \infty$ (or $x \rightarrow -\infty$) and, correspondingly, two heteroclinic points β^+ and β^- on $\widetilde{\mathfrak{R}}^n$ associated with the following values of μ_j :

$$\mu_j = b_j, \quad j = 1, \dots, n. \quad (17)$$

(For details see Alber and Marsden [1994].)

The stable W^s (and unstable W^u) manifolds of the point b are coincident and consist of the orbits in \mathfrak{R}^n that are forward (and backward) asymptotic to the homoclinic point b . On the other hand, the unstable manifold of the point β^+ connects it to the point β^- in $\widetilde{\mathfrak{R}}^n$ and similarly for the stable manifold; these heteroclinic manifolds cover the homoclinic manifold in \mathfrak{R}^n .

4 Solutions with Monodromy for the 2-component Dym System

For the C. Neumann problem, the spectral parameter appears linearly in the potential of the corresponding Schrödinger equation. However, in other systems of interest, this dependence is more complicated. In this section we discuss such systems; specifically, we consider Hamiltonian systems on Riemann surfaces that are associated with energy dependent Schrödinger operators. In these systems, the dependence of the potential on the spectral parameter can have a pole. We also consider N -component systems of equations, using the hierarchy of the 2-component Dym systems as an example. In particular, we construct special solutions with monodromy for these systems of equations.

Using the method described in §2 and §3 with a potential of the form

$$V = u(x, t) + \lambda + \frac{v(x, t)}{\lambda} ,$$

and the dynamical recurrence chain for coefficients b_j obtained from the dynamical generating equation (??) by setting $B(x, \lambda) = b_0(x)\lambda + b_1(x)$ and equating coefficients of the same power of λ , one obtains the following system of coupled pde's which is called the first member of the hierarchy of the 2-component Dym systems,

$$\left. \begin{aligned} \frac{\partial u}{\partial t} &= \frac{1}{4}u''' - \frac{3}{2}uu' + v' , \\ \frac{\partial v}{\partial t} &= -u'v - \frac{1}{2}uv' . \end{aligned} \right\} \quad (1)$$

Notice that the choice of polynomial $B_l(x, \lambda) = b_0(x)\lambda^l + \dots + b_l$ of the l 'th order yields the l 'th integrable system of evolution equations of the 2-component Dym hierarchy.

In what follows, we will introduce a Hamiltonian structure for the set of quasi-periodic solutions of the equations from the hierarchy of 2-component Dym systems. Certain limiting procedures applied to this Hamiltonian system will then yield special solutions with monodromy.

One obtains μ -representations for the l 'th system from the hierarchy after substituting $E = \mu_j$ into the generating equations (??) and (??):

$$\mu_j' = \frac{1}{\prod_{r \neq j}^n (\mu_j - \mu_r)} \sqrt{\frac{C(\mu_j)}{\mu_j}} , \quad j = 1, \dots, n , \quad (2)$$

$$\dot{\mu}_j = \frac{B_l(\mu_j)}{\prod_{r \neq j}^n (\mu_j - \mu_r)} \sqrt{\frac{C(\mu_j)}{\mu_j}} , \quad j = 1, \dots, n , \quad (3)$$

where

$$C(\mu_j) = -L_0^2 \prod_{k=1}^{2n+2} (\mu_j - m_k) ,$$

l labels the number of a system in the 2-component Dym hierarchy, and L_0 is a constant. In the case $l = 1$ one obtains μ -representations for the system (??). Each of the μ -variables is defined on a copy of the Riemann surface

$$\mathfrak{R} : P^2 = \frac{C(\mu)}{\mu} . \quad (4)$$

Recall that the μ variables move along cycles on the corresponding Riemann surface (??) over the basic cuts between m_{2j} and m_{2j-1} , $j = 1, \dots, n$.

Equations (??) and (??) define Hamiltonian systems with the Hamiltonians

$$H = \sum_{j=1}^n \frac{D(\mu_j) \left(P_j^2 - \frac{C(\mu_j)}{\mu_j} \right)}{\prod_{r \neq j}^n (\mu_j - \mu_r)} , \quad (5)$$

where $D(\mu_j) = 1$ and $D(\mu_j) = B_l(\mu_j)$ in the stationary (??) and dynamical (??) cases, respectively. These have the following common set of first integrals

$$P_j^2 = \frac{C(\mu_j)}{\mu_j} , \quad j = 1, \dots, n . \quad (6)$$

Now we construct a system of action-angle variables to linearize quasi-periodic Hamiltonian flows using a method similar to the one described in §3.

Here we are dealing with a degenerate system because, as will be shown below, the genus of the associated Riemann surface is $(n + 1)$ and yet we have only n μ -variables. Related to this, there is also a degeneracy in the problem of inversion.

This degeneracy can be resolved by introducing an additional μ_{n+1} variable, solving the problem of inversion in terms of Riemann Θ functions on the $(n + 1)$ -dimensional Jacobian and then setting μ_{n+1} equal to a constant m_{2n+2} at the end. This is equivalent to projecting a class of solutions of the enlarged $(n + 1)$ -dimensional Hamiltonian system onto a subclass of solutions defined on an n -dimensional subspace in phase space.

After introducing μ_{n+1} into (??) and (??) and adding a pair of equations for the μ'_{n+1} and $\dot{\mu}_{n+1}$, rearranging the resulting system of equations, summing and using Lagrange-type interpolation formulas, one obtains the following expressions

$$\left. \begin{aligned} \sum_{j=1}^{n+1} \frac{\mu_j^{k+1} \mu_j'}{\sqrt{C(\mu_j)\mu_j}} &= \sum_{j=1}^{n+1} \frac{\mu_j^k}{\prod_{r \neq j}^{n+1} (\mu_j - \mu_r)} = \delta_k^{n-1} , \\ \sum_{j=1}^{n+1} \frac{\mu_j^{k+1} \dot{\mu}_j}{\sqrt{C(\mu_j)\mu_j}} &= \sum_{j=1}^{n+1} \frac{\mu_j^k B_2(\mu_j)}{\prod_{r \neq j}^{n+1} (\mu_j - \mu_r)} = \delta_k^{n-2} , \end{aligned} \right\} \quad (7)$$

where δ is the Kronecker delta. After integrating (??), one obtains the action-angle variables:

$$\theta_k = \sum_{j=1}^{n+1} \int_{\mu_j^0}^{\mu_j} \frac{\mu_j^{k+1} d\mu_j}{\sqrt{C(\mu_j)\mu_j}} = \delta_k^{n-1} x + \delta_k^{n-2} t + \theta_k^0 , \quad I_k = c_{2n-k+1} , \quad k = 0, \dots, n , \quad (8)$$

where c_{2n-k+1} are coefficients of the polynomial $C(\mu)$ and θ_k^0 are constants. The above integrals are taken along cycles a_j over basic cuts on the Riemann surface

$$\Re : W^2 = C(\mu)\mu , \quad (9)$$

which has genus $g = n + 1$. The system (??) is equivalent to a Jacobi problem of inversion. It can be solved for $\mu_j, j = 1, \dots, n + 1$ as functions of x and t in terms of Riemann Θ -functions (see for example Ercolani and McKean [1990] and Alber and Alber [1987]). Finally, we obtain the solution of our Hamiltonian system by setting $\mu_{n+1} = m_{2n+2}$.

On the other hand, after setting $m_{2n+2} = m_{2n+1} = b$ in the initial Hamiltonian systems (??) and (??) there is no need to introduce an additional μ variable. This yields in the manner described above, a system of angle variables

$$\theta_k = \sum_{j=1}^{n+1} \int_{\mu_j^0}^{\mu_j} \frac{\mu_j^{k+1} d\mu_j}{(\mu_j - b) \sqrt{\bar{C}(\mu_j)\mu_j}} = \sigma_{k,1}x + \sigma_{k,2}t + \theta_k^0 , \quad k = 0, \dots, n - 1 , \quad (10)$$

where $\bar{C}(\mu_j) = \prod_{k=1}^{2n} (\mu - m_k)$ and $\sigma_{k,1}, \sigma_{k,2}$ are constants. This can be viewed as a problem of inversion with a singularity at $\mu = b$, resulting in a phenomenon of monodromy for the Hamiltonian system which can be demonstrated as follows.

We define a Jacobian fibration with the base parametrized by roots of the basic polynomial $C(\lambda)\lambda$ of the Riemann surface (??). Now, moving b along a certain closed loop in the space of parameters (the base of the fibration) can lead to a nontrivial shift in the action angle variables. Consider first the case $n = 1$. The limiting process $m_3, m_4 \rightarrow b$ applied to the quasi-periodic angle variables yields the angle variable

$$\theta_1 = \int_{\mu_1^0}^{\mu_1} \frac{\mu_1 d\mu_1}{(\mu_1 - b) \sqrt{-\mu_1(\mu_1 - m_1)(\mu_1 - m_2)}} = L_0x + \theta_1^0 . \quad (11)$$

In the case of $n = 2$, the limiting angle variables are as follows

$$\left. \begin{aligned} \theta_1 &= -\frac{\partial S}{\partial \beta_1} = \int_{\mu_1^0}^{\mu_1} \frac{\mu_1 d\mu_1}{(\mu_1 - b) \sqrt{C_5(\mu_1)}} + \int_{\mu_2^0}^{\mu_2} \frac{\mu_2 d\mu_2}{(\mu_2 - b) \sqrt{C_5(\mu_2)}} = \theta_1^0 , \\ \theta_2 &= -\frac{\partial S}{\partial \beta_2} = \int_{\mu_1^0}^{\mu_1} \frac{\mu_1 d\mu_1}{\sqrt{C_5(\mu_1)}} + \int_{\mu_2^0}^{\mu_2} \frac{\mu_2 d\mu_2}{\sqrt{C_5(\mu_2)}} = L_0x + \theta_2^0 , \end{aligned} \right\} \quad (12)$$

where

$$S = \int_{\mu_1^0}^{\mu_1} \frac{\sqrt{C_5(\mu_1)} d\mu_1}{\mu_1 - b} + \int_{\mu_2^0}^{\mu_2} \frac{\sqrt{C_5(\mu_2)} d\mu_2}{\mu_2 - b}$$

is an action function and

$$C_5(\mu) = -\mu(\mu - m_1)(\mu - m_2)(\mu - m_3)(\mu - m_4) .$$

The variables μ_1 and μ_2 move along cycles a_1 and a_2 over the cuts $[m_1, m_2]$ and $[m_3, m_4]$ on the Riemann surface $W^2 = C_5(\mu)$. There is also a singularity at $\mu = b$. Transport of a system

of canonical action-angle variables, which linearize the Hamiltonian flow, along a certain loop in the space of parameters (b, m_j) in a way similar to the case of the spherical pendulum and some other integrable systems with monodromy (see, for example, Duistermaat [1980] and Bates and Zou [1993]) will result in a nontrivial shift, which is a manifestation of the monodromy phenomenon. This can be demonstrated as follows. Canonical actions are calculated in terms of periods of the differential

$$I_j = \oint_{a_j} dS = \oint_{a_j} \frac{\sqrt{C_5(\mu)}d\mu}{\mu - b} ,$$

along cycles a_j on the Riemann surface; for details see Arnold [1978]. Now suppose initially that b does not belong to any of the cycles a_1 and a_2 . Then moving b along a closed loop on the Riemann surface around one of the branch points m_j , one continuously transforms one of the a -cycles. At some moment b becomes a branch point itself, which results in a shift of the action variable that is given by the residue of the integrand at $\mu = b$.

Flaschka, Forest and McLaughlin [1980] proposed the use of μ -representations in calculations of modulation equations and showed that in case of the KdV equation, Whitham theory can be described in terms of holomorphic and meromorphic differentials on the moduli spaces of Riemann surfaces. Namely, they described the slow modulation of branch points of the Riemann surfaces.

The monodromy effect described in this section provides an example of a singularity of Whitham type equations. It has to be taken into account in the investigation of modulational theory of the N -component systems.

5 Mechanical Systems and Nonlinear Equations

In §2 we recalled the link between quasi-periodic solutions of integrable nonlinear equations and Hamiltonian systems on Riemann surfaces established using generating equations and algebraic-geometric methods. Here we expand on this by generating the Euler-Lagrange equations for some well known mechanical problems. This establishes a link between such systems and the stationary Hamiltonian flows for classes of solutions of integrable nonlinear pde's. (See, for example, Alber *et al.* [1994, 1995] for additional information.) This will be used in §6 to study the semiclassical theory of such solutions.

One obtains the Euler-Lagrange equations, using the method of generating equations described in §2 and by changing variables in $B(x, \lambda)$ from μ 's to q 's:

$$B(x, \lambda) = \prod_{i=1}^n (\lambda - \mu_i(x, t)) = \sum_{j=1}^{n+1} \prod_{r=1, r \neq j}^{n+1} (\lambda - l_r) q_j^2(x) . \quad (1)$$

We also denote

$$W(\lambda) = \frac{C(\lambda)}{K(\lambda)} = \frac{\prod_{r=j}^{2n+N} (\lambda - l_j)}{\prod_{j=r}^M (\lambda - a_r)} ,$$

where λ is a complex parameter and the constants l_j and a_r will be shown to be determined by the parameters and first integrals of the particular mechanical system.

The expression (??) can be viewed as a definition of generalized elliptic μ coordinates on Riemann surfaces. Coordinates $q_j^2 = x_j^2/l_j$ are normalized cartesian coordinates of a particular mechanical system. Equating coefficients for the λ^n in (??) yields

$$\sum_{j=1}^{n+1} q_j^2 = \sum_{j=1}^{n+1} \frac{x_j^2}{l_j} = 1 . \quad (2)$$

The parameters l_j can be complex and so (??) defines a pseudo-sphere in \mathbb{C}^{n+1} and provides a constraint for the Euler-Lagrange equations.

In terms of the q -variables, our mechanical problems may be thought of as problems of geodesics on the pseudo-sphere (??) in the presence of a potential. In §6 we link them to the Laplace Beltrami operators in a way similar to the method of geometric optics and study semiclassical approximations for eigenfunctions of Laplace Beltrami operators having the form of complex WKB modes.

Substituting B and V into (??) and setting $\lambda = l_r$ one by one, a system of equations is generated for the functions $q_j(x)$. Below we obtain several different integrable systems for different choices of the potential $V(x, \lambda)$.

Recall (from Moser [1981]) the classical C. Neumann and Jacobi problems. The C. Neumann problem for the motion of a particle on the n -sphere in the field of a quadratic potential corresponds to $V = u(x) - \lambda$. Substituting (??) into (??), and setting $\lambda = l_r$ one by one, yields a system of Euler-Lagrange equations,

$$q_j'' - q_j(u - l_j) = 0 , \quad j = 1, \dots, n + 1 ,$$

corresponding to the Lagrangian

$$L = \sum_{j=1}^{n+1} q_j'^2 + u \left(\sum_{j=1}^{n+1} q_j^2 - 1 \right) - \sum_{j=1}^{n+1} l_j q_j^2 .$$

Notice that the Euler-Lagrange equations and constraint $\sum_{j=1}^{n+1} q_j^2 = 1$ yield the following expression for u :

$$u(x) = \sum_{j=1}^{n+1} l_j q_j^2 - \sum_{j=1}^{n+1} q_j'^2 .$$

The function u plays the role of Lagrange multiplier.

For the Jacobi problem of geodesics on n -dimensional quadrics (free motion on quadrics), one takes

$$V = \frac{u(x)}{\lambda} ,$$

and the Euler-Lagrange equations are

$$q_j'' - q_j \frac{u}{l_j} = 0 ,$$

where l_j are semiaxis of the ellipsoid. Here the Lagrangian and u are as follows

$$L = \sum_{j=1}^{n+1} l_j q_j'^2 + u \left(\sum_{j=1}^{n+1} q_j^2 - 1 \right), \quad u(x) = \frac{\sum_{j=1}^{n+1} q_j'^2}{\sum_{j=1}^{n+1} \frac{q_j^2}{l_j}}.$$

Next we consider a linear combination of the potentials for the C. Neumann and Jacobi problems. (Mechanical systems associated with this potential were discussed in Braden [1982]). Here we are interested in the connection between this problem and the spatial flow for a particular class of solutions of the system of coupled pde's (??).

Here, $V = u(x) + \lambda + v(x)/\lambda$ and the Euler-Lagrange equations are

$$q_j'' - q_j \left(u + l_j + \frac{v}{l_j} \right) = 0,$$

with the constraint $\sum_{j=1}^{n+1} q_j^2 = 1$. The Lagrangian and the potential are as follows:

$$L = \sum_{j=1}^{n+1} q_j'^2 + u \left(\sum_{j=1}^{n+1} q_j^2 - 1 \right) + \sum_{j=1}^{n+1} l_j q_j^2 - \frac{1}{\sum_{j=1}^{n+1} \frac{q_j^2}{l_j}},$$

$$u(x) = - \sum_{j=1}^{n+1} q_j'^2 - \sum_{j=1}^{n+1} l_j q_j^2 + \frac{1}{\sum_{j=1}^{n+1} \frac{q_j^2}{l_j}}.$$

Here we are using

$$v(x) = \frac{1}{\left(\sum_{j=1}^{n+1} \frac{q_j^2}{l_j} \right)^2},$$

which is obtained from a recurrence chain generated by (??).

Now consider the flow for the Camassa-Holm shallow water equation (see Alber *et al.* [1994]). Here

$$V = 1 + \frac{u(x)}{\lambda}$$

and

$$q_j'' - q_j \left(\frac{u}{l_j} + 1 \right) = 0.$$

The Lagrangian and potential are as follows

$$L = \sum_{j=1}^{n+1} q_j'^2 + u \left(\sum_{j=1}^{n+1} q_j^2 - 1 \right) - \frac{1}{\sum_{j=1}^{n+1} \frac{q_j^2}{l_j}}, \quad u(x) = - \sum_{j=1}^{n+1} q_j'^2 + \frac{1}{\sum_{j=1}^{n+1} \frac{q_j^2}{l_j}}.$$

The next example is provided by the spatial flow for a generalization of the shallow water equation. Calogero and Degasperis [1982] studied an interesting new class of integrable mechanical systems. We generalize this class by considering a 2-component case whose

associated system of coupled pde's has the form of a coupled system of equations of shallow water type. Here,

$$V = u(x) + \frac{v(x)}{\lambda},$$

and

$$q_j'' - q_j \left(u + \frac{v}{l_j} \right) = 0.$$

The Lagrangian and potential are as follows

$$L = \sum_{j=1}^{n+1} l_j q_j'^2 + v \left(\sum_{j=1}^{n+1} q_j^2 - 1 \right) - \frac{u}{\sum_{j=1}^{n+1} \frac{q_j^2}{l_j}}, \quad u(x) = - \sum_{j=1}^{n+1} q_j'^2 + \frac{1}{\sum_{j=1}^{n+1} \frac{q_j^2}{l_j}}.$$

See Appendix 1 for the mechanical system associated with the 2-component KdV system.

6 Complex Semiclassical Solutions

Recall that solutions of integrable systems can be reduced to finite-dimensional Hamiltonian systems with the commuting x and t flows as outlined in §2. Hamiltonian flows for a variety of important integrable mechanical systems are constructed using the same techniques and are linked to the spatial flows for particular classes of solutions of the nonlinear pde's.

Each of these flows can be characterized by a Hamiltonian of the form (??). Here we discuss the semiclassical limits of the associated Laplace-Beltrami operators for these systems. In what follows, we recall from Alber [1989, 1991] and Alber and Marsden [1992], a method of complex geometric asymptotics for integrable Hamiltonian flows on Riemann surfaces. We will use geometric asymptotics to describe the quantization conditions of Bohr-Sommerfeld-Keller (BSK) type. Then we will investigate the dependence of these conditions on the parameters (*i.e.*, the first integrals) of the system. This dependence near singularities produces effects caused by the classical and semiclassical monodromy.

Let us consider quadratic complex Hamiltonians of the form (??) defined on \mathbb{C}^{2n} . We think of \mathbb{C}^{2n} as being the cotangent bundle of \mathbb{C}^n , with configuration variables μ_1, \dots, μ_n and with canonically conjugate momenta P_1, \dots, P_n .

Notice that the Hamiltonians for quasi-periodic solutions of the systems considered in the previous sections are indeed of this form. We consider the functions g^{jj} as components of a (diagonal) Riemannian metric, construct the associated Laplace-Beltrami operator, and then the stationary Schrödinger equation

$$\nabla^j \nabla_j U + w^2 (E - V) U = 0, \tag{1}$$

defined on the n -dimensional complex Riemannian manifold \mathbb{C}^n . Here ∇^j and ∇_j are covariant and contravariant derivatives defined by the tensor g^{jj} and w (which is the inverse of Planck's constant \hbar) and E (the energy eigenvalue) are parameters. Note also that in general, the metric tensor is not constant, and even may have singularities, so that the kinetic term in the expression for H is *not* purely quadratic.

Now we establish a link between (??) and the Hamiltonian system (??) by means of geometric asymptotics; namely, we consider the following function that is similar to the well known Ansatz from WKB theory:

$$\begin{aligned} U(z_1, \dots, z_n) &= \sum_k A_k(\mu_1, \dots, \mu_n) \exp[iwS_k(\mu_1, \dots, \mu_n)] , \\ &= \sum_k \prod_{j=1}^n U_{kj}(\mu_j) = \sum_k \prod_{j=1}^n (A_{kj}(\mu_j) \exp[iwS_{kj}(\mu_j)]) , \end{aligned} \quad (2)$$

which is a multivalued function of several complex variables defined on \mathbb{C}^n . If, instead, one considers U to be defined on the covering space of the Jacobi variety of the problem, then U becomes single valued. The functions present in this expression together with r , which denotes a vector of Maslov indices, will be determined below. Note that k also labels the classical paths between initial and current points in the configuration space.

Substituting (??) in (??), equating coefficients for w and w^2 and integrating, we obtain the amplitude function A , which is a solution of the transport equation, in the form

$$A = \frac{A_0}{\sqrt{(D \det J)}} , \quad (3)$$

where $D = \sqrt{\prod_{l=1}^n g_{ll}}$ is the volume element of the metric and J is the Jacobian of the change of coordinates from the μ -representation to the angle θ -representation. We also find that the phase function S is a solution of the Hamilton-Jacobi equation

$$\Delta^j S \Delta_j S - V = E , \quad (4)$$

so that it coincides with the action function. Finally, we describe the dependence of the WKB modes (??) on t as a parameter, by introducing commuting t -flow for the μ variables described by (??).

7 Semiclassical Monodromy

Now we can apply the constructions that have been developed above to the case of the special class of solutions of the 2-potential Dym system for $n = 2$ (see §4). The Hamiltonian and complex geometric asymptotic solution in this case have the form:

$$H = \frac{1}{2} \frac{P_1^2 - \frac{C_5(\mu_1)}{\mu_1 - b}}{\mu_1 - \mu_2} + \frac{1}{2} \frac{P_2^2 - \frac{C_5(\mu_2)}{\mu_2 - b}}{\mu_2 - \mu_1} . \quad (1)$$

and

$$U = \sum_{k=(k_1, k_2)} A_0 \frac{\sqrt{\mu_1 \mu_2}}{((\mu_1 - b)(\mu_2 - b))^{\frac{1}{2}} (C_5(\mu_1)(C_5(\mu_2)))^{\frac{1}{4}}} \exp [iwS_{k_1}(\mu_1) + S_{k_2}(\mu_2)] , \quad (2)$$

where

$$S_{k_1}(z_1) = \int_{\mu_1^0}^{\mu_1} \frac{\sqrt{C_5(\mu_1)} d\mu_1}{\mu_1 - b} + k_1 T_1 + \frac{r_1 \pi}{4}, \quad (3)$$

$$S_{k_2}(z_2) = \int_{\mu_2^0}^{\mu_2} \frac{\sqrt{C_5(\mu_2)} d\mu_2}{\mu_2 - b} + k_2 T_2 + \frac{r_2 \pi}{2}, \quad (4)$$

and where $r = (r_1, r_2)$ is a vector of Maslov indices and

$$\left. \begin{aligned} T_1 &= \oint_{a_1} \frac{\sqrt{C_5(\mu_2)} d\mu_2}{\mu_2 - b}, \\ T_2 &= \oint_{a_2} \frac{\sqrt{C_5(\mu_2)} d\mu_2}{\mu_2 - b}. \end{aligned} \right\} \quad (5)$$

The amplitude A has singularities at the branch points $\mu_1 = m_1, m_2$, $\mu_2 = m_3, m_4$ and at an additional singular point b on the associated Riemann surface. Each time a trajectory approaches one of these singularities, we continue it to complex x and go around a small circle in the complex plane enclosing the singularity. This results in a phase shift ($\pm i\pi/2$) of the phase function S , which is common in geometric asymptotics. The indices k_1 and k_2 keep track of the number of oriented circuits for μ_1 and μ_2 around a_1 and a_2 . The complex mode (??) is defined on the covering space of the complex Jacobi variety. Note that in the real case, this complex mode is defined on the covering space of a real subtorus. Keeping this in mind, quantum conditions of BSK type can be imposed as conditions on the number of sheets of the covering space of the corresponding Riemann surface for each coordinate μ_1 and μ_2 :

$$\left. \begin{aligned} \frac{\pi}{2} r_1 + w k_1 T_1 &= 2\pi N_1, \\ \frac{\pi}{2} r_2 + w k_2 T_2 &= 2\pi N_2. \end{aligned} \right\} \quad (6)$$

Here N_1, N_2 are integer quantum numbers related to each other and to integer indices k_1, k_2 and r_1, r_2 as follows

$$w = \frac{2\pi N_1}{k_1 T_1} = \frac{1}{k_2 T_2} \left(2\pi N_2 - \frac{\pi r_2}{2} \right), \quad (7)$$

which is an asymptotic formulae for the eigenvalues of the stationary Schrödinger equation (??). (For details about Maslov-Keller indices and quantum conditions see amongst others Robbins [1991] and Alber [1989, 1991].) Maslov-Keller indices play an important role in numerical study of the semiclassical limit of the NLS equations presented in Jin, Levermore and McLaughlin [1994].

Notice that the quantum conditions (??) include a monodromy part after transport along a closed loop in the space of parameters.

8 The Stationary Schrödinger Equation, Bloch functions and Complex WKB Solutions

Lastly we contrast semiclassical approximations for the Bloch eigenfunctions to the approach of §6 which uses a Riemannian metric associated with the complex Hamiltonian system associated with finite-dimensional solution space.

Namely we show how to obtain semiclassical approximations for the Bloch eigenfunctions of the operators defined in (??) and (??) and used in the inverse scattering transform theory (see Ablowitz and Segur [1981]). The equation (??) is a natural generalization of a one-dimensional stationary Schrödinger equation

$$-\frac{\hbar^2}{2m} \frac{\partial^2 \psi}{\partial x^2} + (V(x) - \lambda)\psi = 0 , \quad (1)$$

which we rewrite

$$-\frac{\partial^2 \psi}{\partial x^2} + V(x, \lambda, \epsilon)\psi = 0 , \quad (2)$$

where

$$V(x, \lambda, E) = \frac{U(x, \lambda)}{\epsilon} , \quad U(x, \lambda) = 2m(u(x) - \lambda) , \quad (3)$$

and $\epsilon = \hbar^2$. In our notation ϵ will be the complex parameter, and we will treat it independently from the energy λ . As usual, the WKB method is used to approximate ψ for small values of the parameter ϵ . In what follows we will use (??) to demonstrate semiclassical theory for the operators defined in (??).

We look for a solution of (??) in the form of a Bloch function

$$\psi = \sqrt{\frac{B}{B_0}} \exp\left(\pm \int_{x_0}^x \frac{\sqrt{C}}{B} dx\right) , \quad (4)$$

where $B = B(x, \epsilon)$ is a function of x and ϵ , $C = C(\epsilon)$ is a function of ϵ , and B_0 is a constant defined by the initial data. This gives a solution of (??) if and only if

$$-B''B + \frac{B'^2}{2} + 2B^2V = C , \quad (5)$$

as can be checked by direct substitution. This equation was first obtained in connection with the KdV equation in Gelfand and Dikey [1975] by investigating asymptotics of resolvents of the Sturm-Liouville equations.

Notice that (??) is just the stationary generating equation (??). We choose $B(x, \epsilon)$ in the form of a polynomial of ϵ and $C(\epsilon)$ to be a rational function with constant coefficients:

$$B(x, \epsilon) = \sum_{l=0}^n b_l(x)\epsilon^{n-l} , \quad C(\epsilon) = \frac{1}{\epsilon} \sum_{k=0}^{2n} c_k \epsilon^{2n-k} . \quad (6)$$

The equation (??) with potential (??) coincides with the generating equation for the geodesic flow on an n -dimensional quadric. It was shown (see Cewen [1990] and Alber

et al. [1994, 1995]) to provide an x -flow for a partial differential equation of Dym type. The equation (??) yields a chain of recurrence relations between the coefficients b_l and c_k . (for details see Alber *et al.* [1994, 1995]). In particular we have

$$V = \frac{c_{2n}}{b_n^2} ,$$

and therefore

$$b_n = \sqrt{\frac{c_{2n}}{2m(V - E)}} .$$

As $\epsilon \rightarrow 0$, the functions $C(\epsilon)$ and $B(\epsilon)$ are asymptotic to $\frac{c_{2n}}{\epsilon}$ and b_n . This yields the following asymptotics for the Bloch function

$$\psi = \frac{\psi_0}{(u - E)^{\frac{1}{4}}} \exp \left(\pm \frac{i}{\sqrt{\epsilon}} \int_{x_0}^x \sqrt{2m(u - E)} dx \right) , \quad (7)$$

which is precisely a well-known WKB solution of the one-dimensional Schrödinger equation (??). A similar procedure produces asymptotics for Bloch functions corresponding to potentials with poles can be carried out using recurrence relations and geodesic flows on the associated Riemann surfaces. For example, a WKB solution in the case of the 2-potential Dym system described above has the form

$$\psi = \frac{\psi_0}{v^{\frac{1}{4}}} \exp \left(\pm \frac{i}{\sqrt{\epsilon}} \int_{x_0}^x \sqrt{2mv} dx \right) . \quad (8)$$

The Bloch function contains all necessary information about the finite gap spectrum and the associated Riemann surfaces. It is an ideal object for applying zero-dispersion limit theory. In the future, we intend to apply this approach to the semiclassical theory of (d)NLS and (f)NLS equations.

9 Conclusions

In this paper we have used so-called energy dependent Schrödinger operators to establish a link between special classes of solutions of N -component systems of evolution equations and finite dimensional Hamiltonian systems on moduli spaces of Riemann surfaces. This yields in particular, a new class of solutions with monodromy for N -component systems of pde's.

We also have used a connection between classes of solutions of nonlinear equations and finite dimensional mechanical systems to investigate the semiclassical theory of nonlinear equations. In the future, we intend to apply this approach for WKB-theory for the equations (??) and (??) in connection with the the zero-dispersion limit of N -component systems such as the coupled NLS equations.

10 Appendix 1

1. (The spatial flow for the 2-component KdV system.) The discrete version of this system corresponds to the Toda and relativistic Toda lattices. (For details see Alber [1987].) Here

$$V = \lambda^2 + v(x)\lambda + u(x) ,$$

and the Euler-Lagrange equations are

$$q_j'' - q_j (u + vl_j + l_j^2) = 0 .$$

The Lagrangian and potential are as follows

$$L = \sum_{j=1}^{n+1} q_j'^2 + u \left(\sum_{j=1}^{n+1} q_j^2 - 1 \right) - \left(\sum_{j=1}^{n+1} l_j q_j^2 \right)^2 - \sum_{j=1}^{n+1} l_j^2 q_j^2 ,$$

$$u(x) = - \sum_{j=1}^{n+1} q_j'^2 + \sum_{j=1}^{n+1} l_j q_j^2 + \left(\sum_{j=1}^{n+1} l_j q_j^2 \right)^2 + \sum_{j=1}^{n+1} l_j^2 q_j^2 .$$

Here we are using the expression

$$v(x) = 2 \sum_{j=1}^{n+1} l_j q_j^2 ,$$

which is obtained from the recurrence chain generated by (??) with $K = 0$. Using the recurrence chain generated by the dynamical generating equation (??) and setting $B(x, \lambda) = b_o(x)\lambda + b_1(x)$ one obtains the following integrable system of coupled pde's of KdV type:

$$\left. \begin{aligned} \frac{\partial u}{\partial t} &= \frac{1}{4}v''' - v'u - \frac{1}{2}vu' , \\ \frac{\partial v}{\partial t} &= u' - \frac{3}{2}vv' . \end{aligned} \right\} \quad (1)$$
