# Preface

These notes serve as a supplement to *Feedback Systems* by Åström and Murray [ÅM21] and expand on some of the topics introduced there. They are motivated by the increasing role of online optimization in feedback systems. This is a change from the traditional use of optimization in control theory for *offline* design of control laws and state estimators. Fueled by Moore's law and improvements in real-time algorithms, it is now possible to perform estimation and control design algorithms online, allowing the system to better account for nonlinearities and to adapt to changes in the underlying dynamics of the controlled process. This changes the way that we think about estimation and control since it allows much greater flexibility in the design process and more modularity and flexibility in the overall system.

Our goal in this supplement is to introduce the essential formalisms and tools required to design optimization-based controllers. Key topics include real-time trajectory generation using differential flatness, the maximum principle, receding horizon optimal control, stochastic processes, Kalman filtering, moving horizon estimation, and (distributed) sensor fusion. While these topics might normally constitute separate textbooks, in this set of notes we attempt to present them in a compact way that allows them to be used in engineering design. We also briefly survey additional advanced topics through the text, with pointers to further information for interested readers.

The various mathematical techniques that are described have been implemented in the Python Control Systems Library (python-control), which is available online at <http://python-control.org>. Most chapters have a section describing the relevant python-control module that implements the topics of the chapter, and exercises are included to allow students to explore various concepts using python-control to carry out numerical calculations. Files associated with these exercises can be downloaded from the relevant portion of the *Feedback Systems* website:

<https://fbswiki.org/OBC>

This supplement has been used in a second quarter controls course at Caltech, taken by a mixture of advanced undergraduates and beginning graduate students with interest in a variety of application areas. The first half of the 10 week course focuses on trajectory generation and optimal control, ending with receding horizon control. In the second half of the course, we introduce stochastic processes and derive the Kalman filter and its various extensions, including the information filter and sensor fusion. The prerequisites for the course are based on the material covered in *Feedback Systems*, including basic knowledge in Lyapunov stability theory

and observers. If needed, these topics can be inserted at the appropriate point in covering the material in this supplement, though they can generally be omitted for a class focused primarily on applications of the concepts.

The notation and conventions in the book follow those used in the main text. Because the notes may not be used in their entirety or in the order presented here, we have attempted to write each chapter as a standalone extension of topics that are briefly introduced in *Feedback Systems*. To this end, each chapter starts with a short description of the prerequisites for the chapter and citations to the relevant literature. Advanced sections, marked by the “dangerous bend” symbol shown in the margin, contain material that requires a slightly more technical background, of the sort that would be expected of graduate students in engineering. Additional information is available on the *Feedback Systems* website:

# Contents

<b>1</b>	<b>Introduction</b>	<b>1-1</b>
1.1	System and Control Design . . . . .	1-1
1.2	The Control System “Standard Model” . . . . .	1-5
1.3	Layered Control Systems . . . . .	1-7
1.4	The Python Control Systems Library . . . . .	1-10
<b>2</b>	<b>Trajectory Generation and Tracking</b>	<b>2-1</b>
2.1	Two Degree of Freedom Design . . . . .	2-1
2.2	Trajectory Tracking and Gain Scheduling . . . . .	2-3
2.3	Trajectory Generation and Differential Flatness . . . . .	2-7
2.4	Python Implementation . . . . .	2-13
2.5	Other Methods for Generating Trajectories . . . . .	2-15
2.6	Further Reading . . . . .	2-17
<b>3</b>	<b>Optimal Control</b>	<b>3-1</b>
3.1	Review: Optimization . . . . .	3-1
3.2	Optimal Control of Systems . . . . .	3-4
3.3	Examples . . . . .	3-8
3.4	Python Implementation . . . . .	3-10
3.5	Linear Quadratic Regulators . . . . .	3-11
3.6	Choosing LQR weights . . . . .	3-15
3.7	Advanced Topics . . . . .	3-16
3.8	Further Reading . . . . .	3-19
<b>4</b>	<b>Receding Horizon Control</b>	<b>4-1</b>
4.1	Overview . . . . .	4-1
4.2	Receding Horizon Control with Terminal Cost . . . . .	4-4
4.3	Implementation in Python . . . . .	4-13
4.4	Receding Horizon Control Using Differential Flatness . . . . .	4-15
4.5	Choosing Cost Functions . . . . .	4-17
4.6	Implementation on the Caltech Ducted Fan . . . . .	4-20
4.7	Further Reading . . . . .	4-28
<b>5</b>	<b>Stochastic Systems</b>	<b>5-1</b>
5.1	Brief Review of Random Variables . . . . .	5-1
5.2	Introduction to Random Processes . . . . .	5-8

5.3	Continuous-Time, Vector-Valued Random Processes . . . . .	5-11
5.4	Linear Stochastic Systems with Gaussian Noise . . . . .	5-14
5.5	Random Processes in the Frequency Domain . . . . .	5-17
5.6	Further Reading . . . . .	5-19
<b>6</b>	<b>Kalman Filtering</b>	<b>6-1</b>
6.1	Linear Quadratic Estimators . . . . .	6-1
6.2	Extensions of the Kalman Filter . . . . .	6-4
6.3	LQG Control . . . . .	6-6
6.4	Application to a Thrust Vectored Aircraft . . . . .	6-7
6.5	Further Reading . . . . .	6-9
<b>7</b>	<b>Sensor Fusion</b>	<b>7-1</b>
7.1	Discrete-Time Stochastic Systems . . . . .	7-1
7.2	Kalman Filters in Discrete Time (FBS2e) . . . . .	7-3
7.3	Predictor-Corrector Form . . . . .	7-4
7.4	Sensor Fusion . . . . .	7-6
	<b>Bibliography</b>	<b>B-1</b>
	<b>Index</b>	<b>I-1</b>
