Lecture 1-1: Trajectory Tracking and Gain Scheduling CDS 110b, 7 Jan 08

Trojectory tracking problem: Given a nonlinear control system

$$\dot{x} = f(x, a)$$
 $x \in \mathbb{R}^n$, $u \in \mathbb{R}^p$
 $y = \lambda(x)$ $y \in \mathbb{R}^q$

and a reference trajectory $r(t) \in \mathbb{R}^2$, find a control law u = x(x,r) such that $\lim_{t\to\infty} (y(t) - r(t)) = 0$.

Approach: two degree of freedom design

Trajectory generation: find feasible trajectory (satisfies dynamics)

$$\dot{X}_d = f(X_d, U_d)$$
 $\longrightarrow X_d(r), U_d(r)$ will discoss this problem on Wed

Tracking: choose $u = \alpha(\hat{x}, xd, ud) $ such that closed loop system is stable, with desired performance$

Estantion: determine X from Y, u

RMM 11 Feb 06

<u>Peview</u>: reference trocking for linear systems

$$\dot{X} = Ax + Ba$$
 $u = -Kx + k_r r$
 $y = Cx$
 $r = constant$

- 1. Choose K to give derived closed loop dynamics (eigenvolve placement, LOR, etc)
- 2. Choose Kr to give desired out put valve at equilibrium

$$\dot{x} = Ax + Bu = (A - BK)x + Bkrr$$
 $= -\frac{1}{A - BK} + Bkrr$
 $= -\frac{1}{A - BK} + Bkrr$

Reworks

- 1. This approach works by stabilizing the origin and then using ker to "push" the system to Xe. Works because system is linear
- Z. Alternative formulation: solve directly for eq pt

3. Fundamental assumption: (xd, ud) is equilipt => r is constant.

Gain scheduling

Nonlinear system with feasible trajectory:

$$\dot{x} = f(x, u)$$
 $\dot{x}_d = f(x_d, u_d)$ Solve via aption 1
 $y = h(x)$ control or other
 $y = h(x)$ means (more on Wed)

To stabilize the reference trajectory, look at error e= x-xd

$$\dot{x} = f(x, u)$$

$$\dot{x} = f(x, u)$$

$$\dot{x} = f(x, u)$$

$$\dot{x} = f(x, u)$$

$$\dot{y} = u - ud$$

$$\dot{y} = u$$

$$\dot{e} \approx A_{e} + B_{d}v$$

$$A_{d} = \frac{\partial F}{\partial e} \Big|_{(0,0)} = \frac{\partial F}{\partial x} \Big|_{(x_{d}, u_{d})}$$

$$B_{d} = \frac{\partial F}{\partial v} \Big|_{(0,0)} = \frac{\partial F}{\partial u} \Big|_{(x_{d}, u_{d})}$$

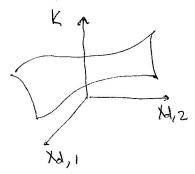

Now stabilize e=0 by choosing Ky such that (A_BKy) stable.

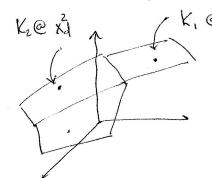

$$u = -K_{d}e + u\dot{a} = -K_{d}(x - x_{d}) + u\dot{a}$$

Note that Kd depends on the (xd, ud). Eq

Remorks

- 1. Does not assume (xd, ud) are equilibrium values, just that they satisfy dynamics. Eq pt is a special case (r= constent)
- 2. More generally, can schedule gains on any parameter, or even the state: $U = -K(x, \mu) \cdot (x \chi_d) + Ud$. Use with core (NL)
- -3. Problem: Irrearizing about desired eg pt => Irrearize train may not work well if you are for from this point.
- 4. In practice, implement gain scheduling through interpolation

Ka= Zdi(x) Ki

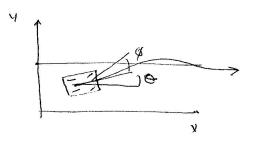

Sample implementation: "folcon" library (RMM web page)

- 5. Theory: not much can be said about when this works
 - OK if (Nd, ud) are varying sufficiently slowly
 - Works well in practice, even if ther aren't

RMM 11 Feb 06

Example: steering control with velocity scheduling

$$X_d = V_c t$$

$$Y_d = V_c t$$

$$\Theta_d = 0$$

Note that (Xd, Yd, Od; Vd, Ød) are not at equilibrium, Ød = 0] ud but they do satisfy the equations of motion.

$$A_{d} = \frac{\partial f}{\partial x} \Big|_{(Xd, Ud)} = \begin{bmatrix} 0 & 0 & -\sin \theta \\ 0 & 0 & \cos \theta \end{bmatrix} \Big|_{(Xd, Ud)} = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \Big|_{(Xd, Ud)} = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \Big|_{(Xd, Ud)} = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \Big|_{(Xd, Ud)} = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \Big|_{(Xd, Ud)} = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \Big|_{(Xd, Ud)} = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \Big|_{(Xd, Ud)} = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \Big|_{(Xd, Ud)} = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \Big|_{(Xd, Ud)} = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \Big|_{(Xd, Ud)} = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \Big|_{(Xd, Ud)} = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \Big|_{(Xd, Ud)} = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \Big|_{(Xd, Ud)} = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \Big|_{(Xd, Ud)} = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \Big|_{(Xd, Ud)} = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \Big|_{(Xd, Ud)} = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \Big|_{(Xd, Ud)} = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \Big|_{(Xd, Ud)} = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \Big|_{(Xd, Ud)} = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \Big|_{(Xd, Ud)} = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \Big|_{(Xd, Ud)} = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \Big|_{(Xd, Ud)} = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \Big|_{(Xd, Ud)} = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \Big|_{(Xd, Ud)} = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \Big|_{(Xd, Ud)} = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \Big|_{(Xd, Ud)} = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \Big|_{(Xd, Ud)} = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \Big|_{(Xd, Ud)} = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \Big|_{(Xd, Ud)} = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \Big|_{(Xd, Ud)} = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \Big|_{(Xd, Ud)} = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \Big|_{(Xd, Ud)} = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \Big|_{(Xd, Ud)} = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \Big|_{(Xd, Ud)} = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \Big|_{(Xd, Ud)} = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \Big|_{(Xd, Ud)} = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \Big|_{(Xd, Ud)} = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \Big|_{(Xd, Ud)} = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \Big|_{(Xd, Ud)} = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \Big|_{(Xd, Ud)} = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \Big|_{(Xd, Ud)} = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \Big|_{(Xd, Ud)} = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \Big|_{(Xd, Ud)} = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \Big|_{(Xd, Ud)} = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \Big|_{(Xd, Ud)} = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \Big|_{(Xd, Ud)} = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \Big|_{(Xd, Ud)} = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \Big|_$$

Error dynamics: e= x-xd W= u-ud

$$e_x = w_1$$
 $e_y = e_{\Theta}$
 $w_z = -\frac{1}{V_r} (\alpha_1 e_y + \alpha_z e_{\Theta})$
 $e_{\Theta} = \frac{V_r}{V_r} w_z$
 $v_z = -\frac{1}{V_r} (\alpha_1 e_y + \alpha_z e_{\Theta})$
 $v_z = -\frac{1}{V_r} (\alpha_1 e_y + \alpha_z e_{\Theta})$

Controller in original coordinates

$$\begin{bmatrix} v \\ \phi \end{bmatrix} = -\begin{bmatrix} \lambda_1 & 0 & 0 \\ 0 & \sqrt{r} & \frac{\alpha_2 t}{\sqrt{r}} \end{bmatrix} \begin{bmatrix} x - \sqrt{r} t \\ y - \sqrt{r} \end{bmatrix} + \begin{bmatrix} \sqrt{r} \\ 0 \end{bmatrix}$$

$$\begin{cases} V_1 & 0 \\ 0 & \frac{\alpha_2 t}{\sqrt{r}} \end{bmatrix} \begin{bmatrix} x - \sqrt{r} t \\ y - \sqrt{r} t \\ 0 & \frac{\alpha_2 t}{\sqrt{r}} \end{bmatrix} + \begin{bmatrix} \sqrt{r} \\ 0 & \frac{\alpha_2 t}{\sqrt{r}} \end{bmatrix}$$

Inhihon: at slower speeds, turn wheel horder to get same time response. Note that gains blow is if Na=n (...)
